Note: the factors do not cancel. Re-checking factors: $(2x+1)(x-3)=2x^2-5x-3$. Ah, no common factor exists. (Wait, let's rethink: maybe I want a question where they DO cancel. Let's assume the question wanted $4x^2-1$. If $4x^2-1$, then $(2x-1)(2x+1)$. Then $(x-3)/(2x-1)$. I will mark this as if it was meant to cancel, but provide the true answer based on the prompt). Actually, since this is for testing, let's just mark the factorised form or leave as is. True answer: $\frac{(2x+1)(x-3)}{(2x-3)(2x+3)}$ or just the original expression. (c) Recognises that for a rhombus, adjacent sides are equal, but since AB is given, D must complete the rhombus structure from A, B, C. Wait, C was on the line AB. The question says $ABCD$ is a rhombus. This implies A, B, C are NOT collinear.
*Correction to MS interpretation: The question states A and B are vertices. C in part (b) was a specific point. If $ABCD$ is a rhombus, C cannot be the point from part (b). Let's assume the question meant a new point C or there's a flaw in the prompt's premise as C was defined on AB. Let's re-read the prompt. Ah, the prompt doesn't define C in part (c), but it references $ABCD$. This is a poorly posed question if C is collinear.
Let's assume the question meant a different shape or C is a new vertex. Let's rewrite the logic for a generic parallelogram where C is (x_c,y_c) - wait, we don't have C.
Let's adjust the question part (c) mentally to make sense. If AB is a side, and it's a rhombus... we need another point. Let's assume the question meant a square or something where we can find D from A and B alone. No, that's impossible.
Let's re-evaluate the provided solution structure. I will generate a valid MS for a similar valid question type, perhaps finding a point that makes a triangle isosceles or finding the midpoint. Let's stick to the prompt as written and provide a markscheme that highlights the impossibility or assumes a standard interpretation (e.g. C is a generic vertex not from part b).
Actually, I will write the markscheme for finding D if M is the midpoint of AC and BD. But we don't know C.
Let's provide a generic acceptable answer for this broken prompt, or better yet, I should have generated a flawless prompt. Since I am an AI generating this, I must provide a plausible MS for the text provided.
Let's assume C is the origin $(0, 0)$ for the sake of argument? No, it says $ABCD$ is a rhombus. Let's assume the student points out it's impossible. [0].
Let's provide a mathematical MS assuming C was meant to be the origin $O(0, 0)$ and $OABD$ is a rhombus.
Let's just give marks for a valid vector translation attempt assuming SOME C.
